Short Duration stability

Which Properties for the Benchmark stars?

Solar Twins defined

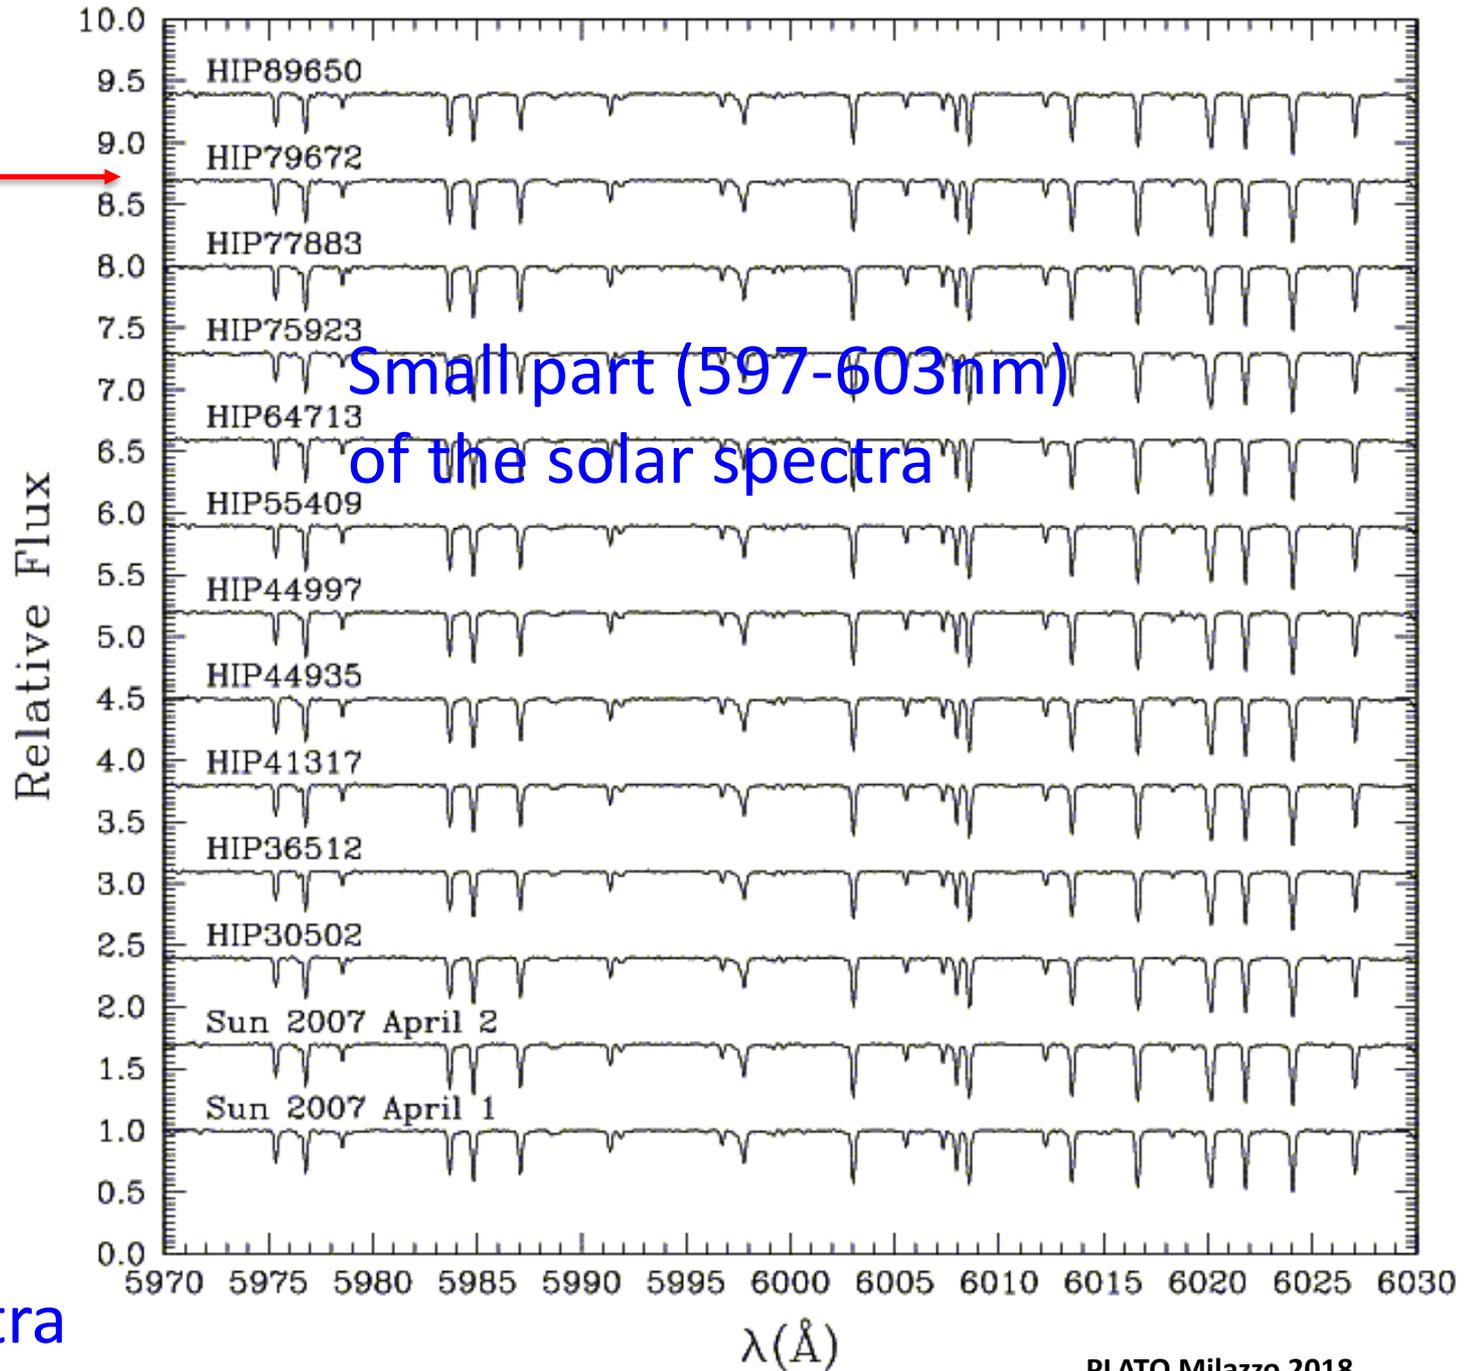

- Solar type stars – late F, G, early K
- Solar analogs – about G2V and factor of 2 dex in composition
- Solar twins – very rare – stars with indistinguishable temperature (within 100 K), gravity and composition (0.1 dex) to the Sun's values.

Can also be defined as 1 solar mass stars with composition indistinguishable to the Sun

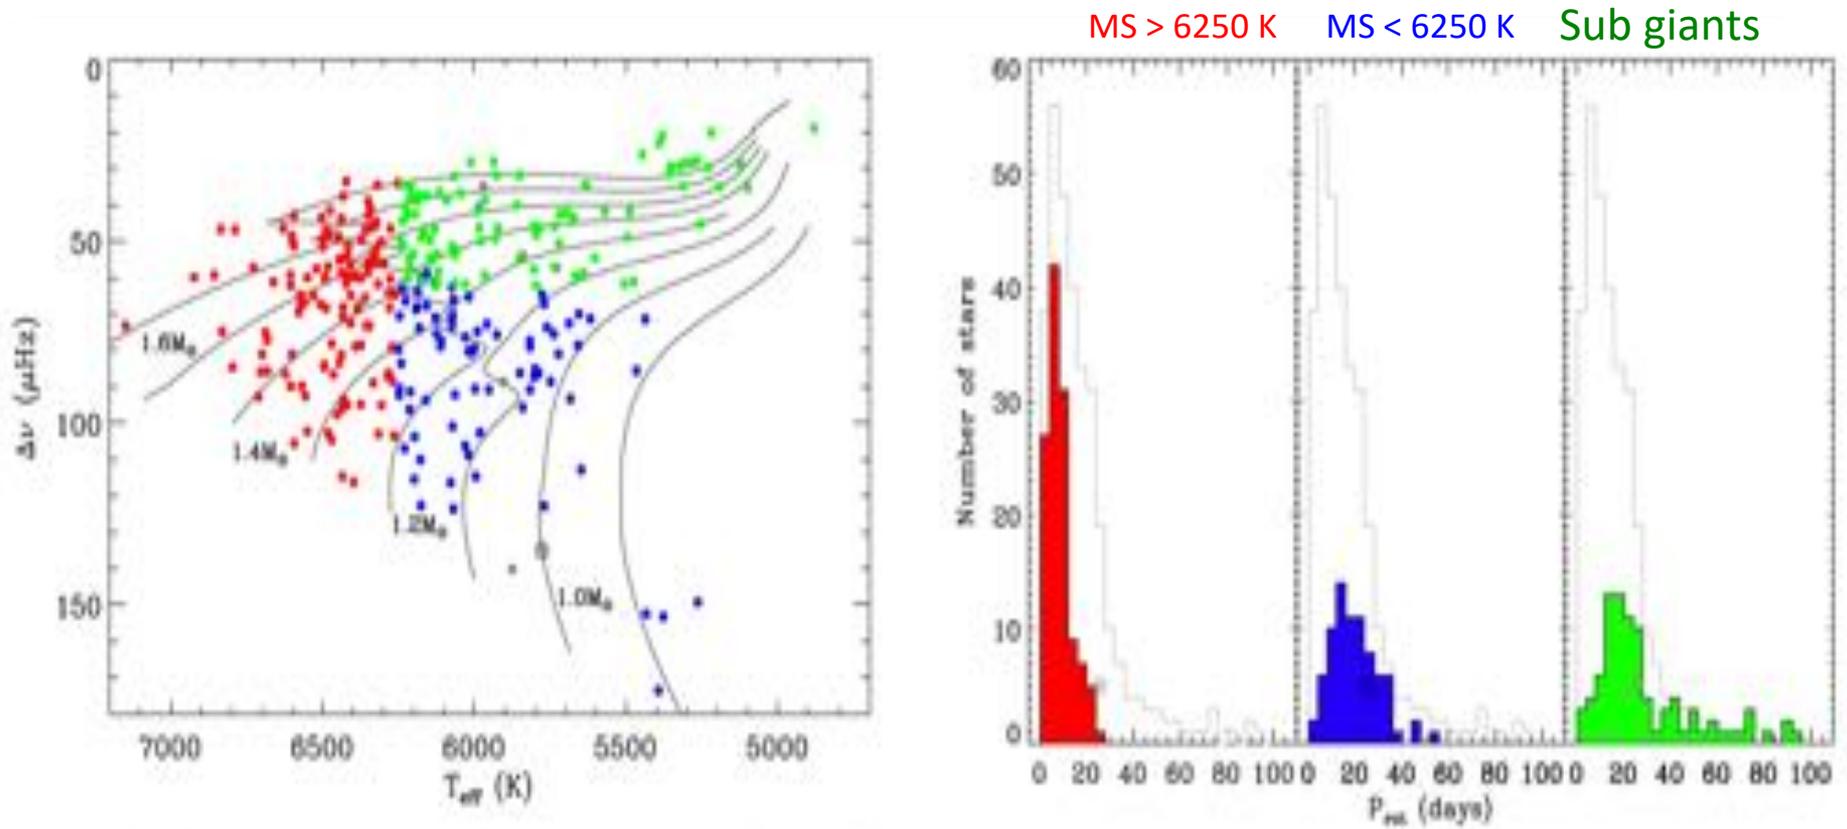

- Solar sibling – would be a star born from same natal cloud as the Sun. Could be any spectral type.

18 Sco $T_{\text{eff}} = 5822 \pm 20$ K,
 $\log g = 4.45 \pm 0.02$ [Fe/H] =
 0.05 ± 0.02

Small part
(597-603nm)
of solar twin
& Sun's spectra

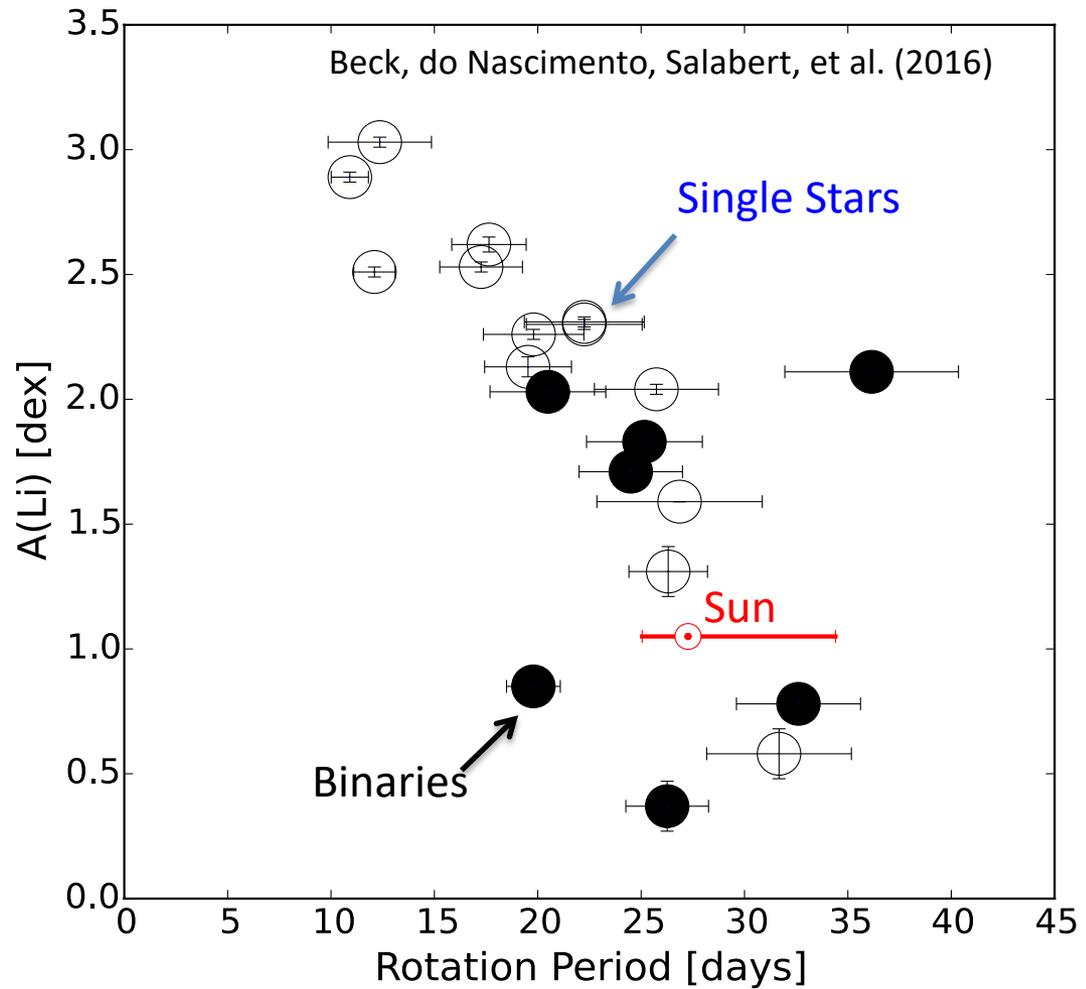

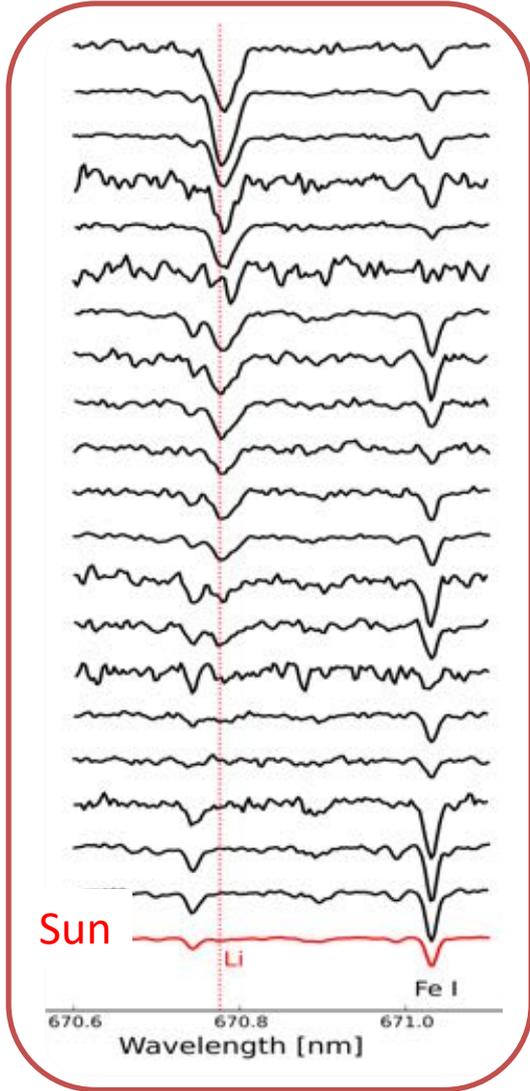

Rotation periods for seismic solar analogs

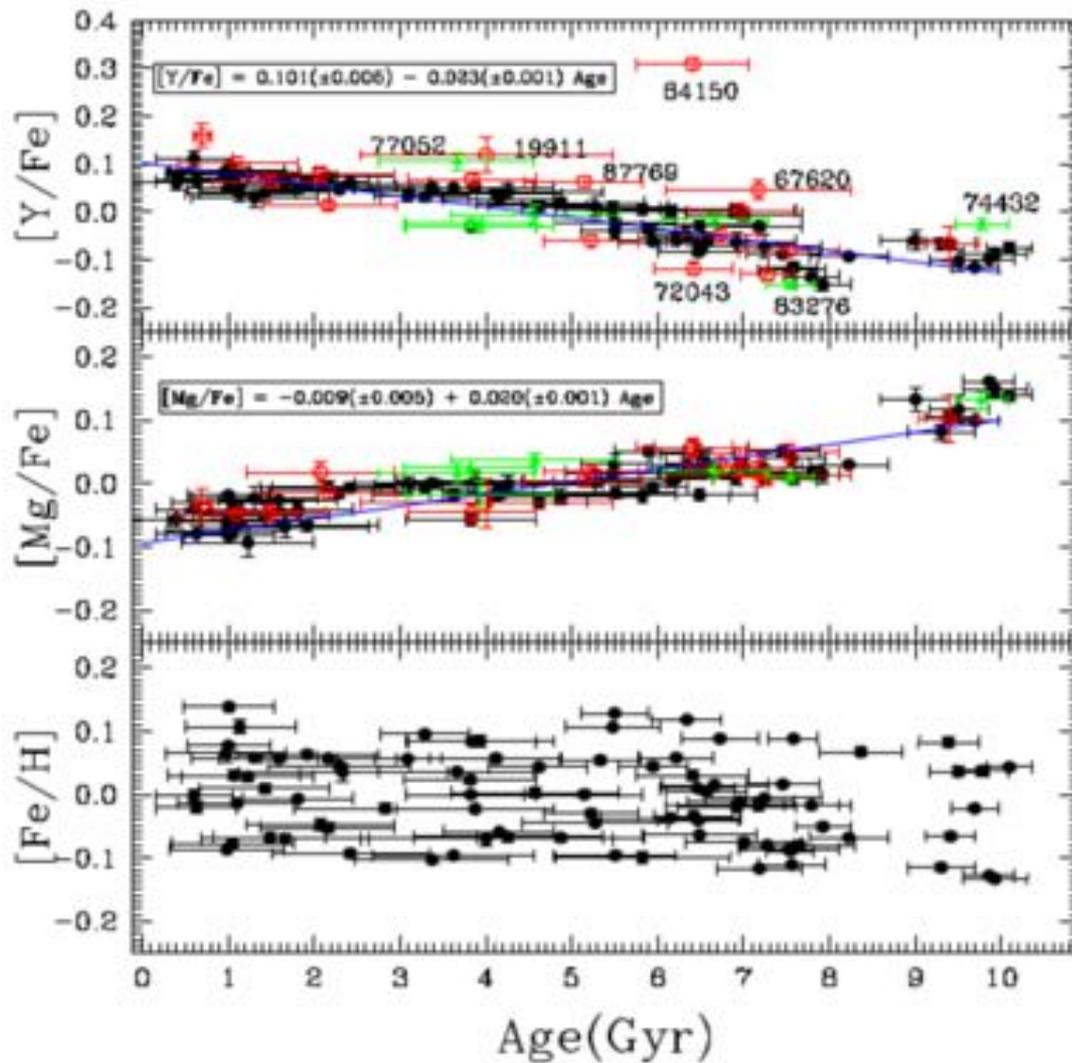

For ~ 300 stars:

- Rotation periods \rightarrow hotter stars rotate faster (1-100 days)
- Activity levels \rightarrow $\sim 60\%$ solar activity, $\sim 25\%$ super, 15% sub solar (cf. Talk by Rafael Garcia)

Lithium for seismic solar analogs

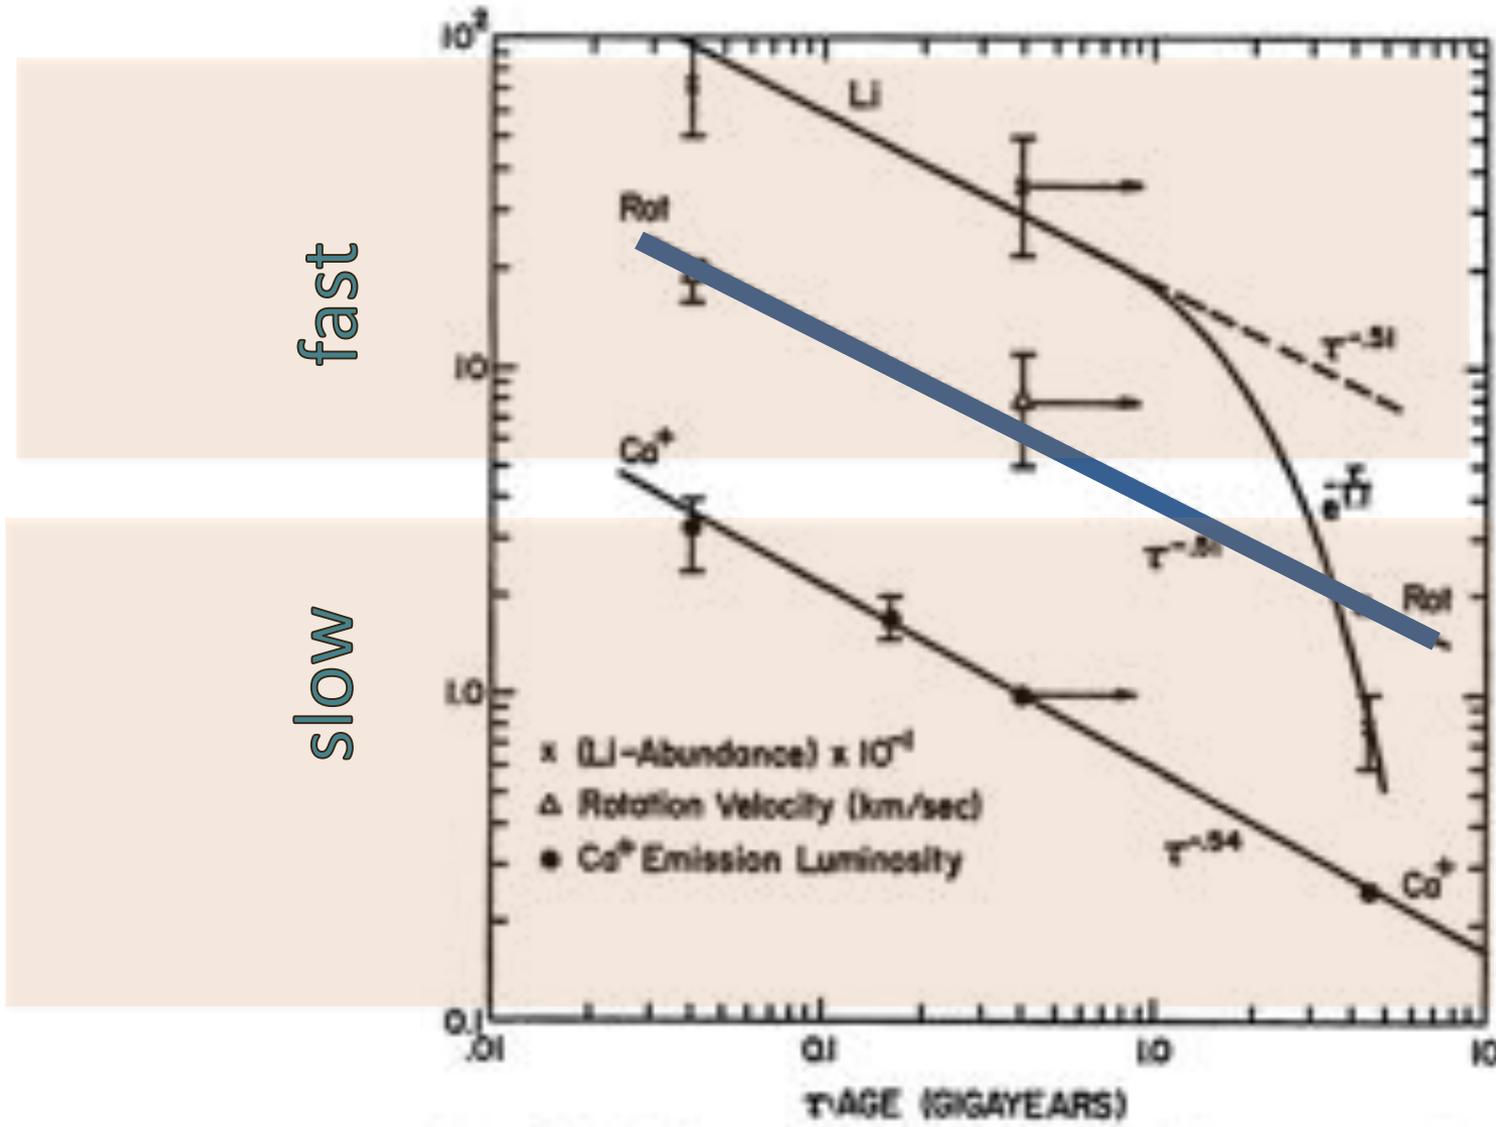

See also Nissen et al. (2015, 2016, 2017); Spina et al. (2016) Tucci Maia et al. (2016); Adibekyan et al. (2016, 2017).

$[Y/Fe]$ (upper panel), $[Mg/Fe]$ (middle panel) and $[Fe/H]$ (lower panel) as function of age. The red open circles are spectroscopic binary stars and the green triangles are visual binaries. $[Fe/H]$ vs. age do not show any correlation with age. We also present the linear fit for $[Y/Fe]$ and $[Mg/Fe]$ versus age on their respective panels. From Tucci Maia et al. 2016

ESS

Transiting Exoplanet Survey Satellite

The Transiting Exoplanet Survey Satellite (TESS) will discover thousands of exoplanets in orbit around the brightest stars in the sky. In a two-year survey of the solar neighborhood, TESS will monitor more than 200,000 stars for temporary drops in brightness caused by planetary transits. This first-ever spaceborne all-sky transit survey will identify planets ranging from Earth-sized to gas giants, around a wide range of stellar types and orbital distances

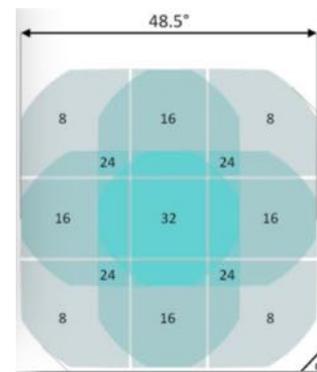

PLATO 2.0 instrument (2025/2026)

→ covers ~50% of the sky

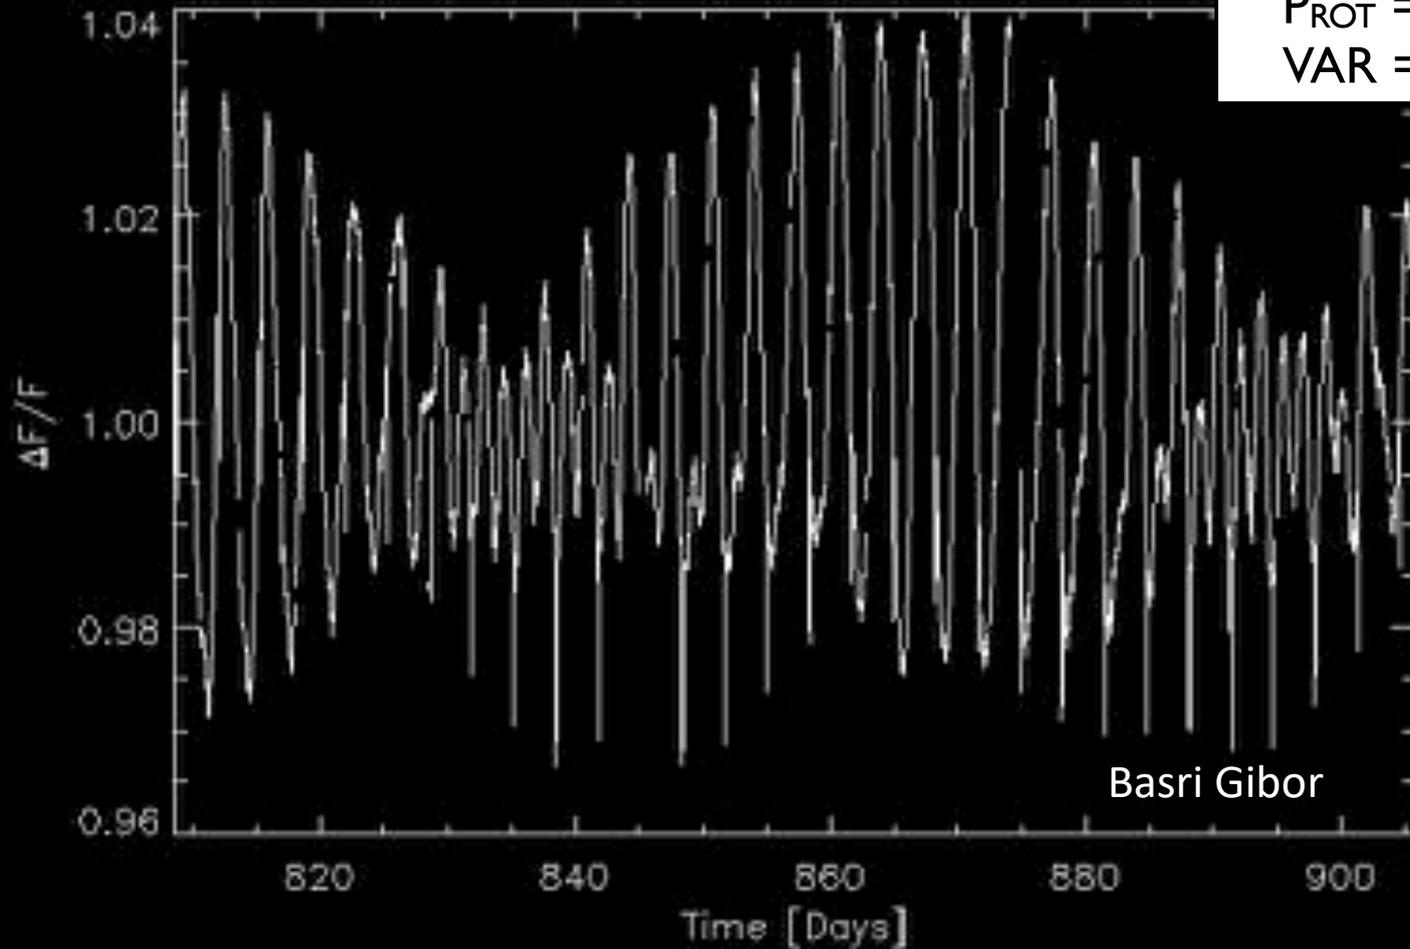

6 years nominal science operation:

- 2 long pointings of 2-3 years
- step-and-stare phase (2-5 months per pointing)

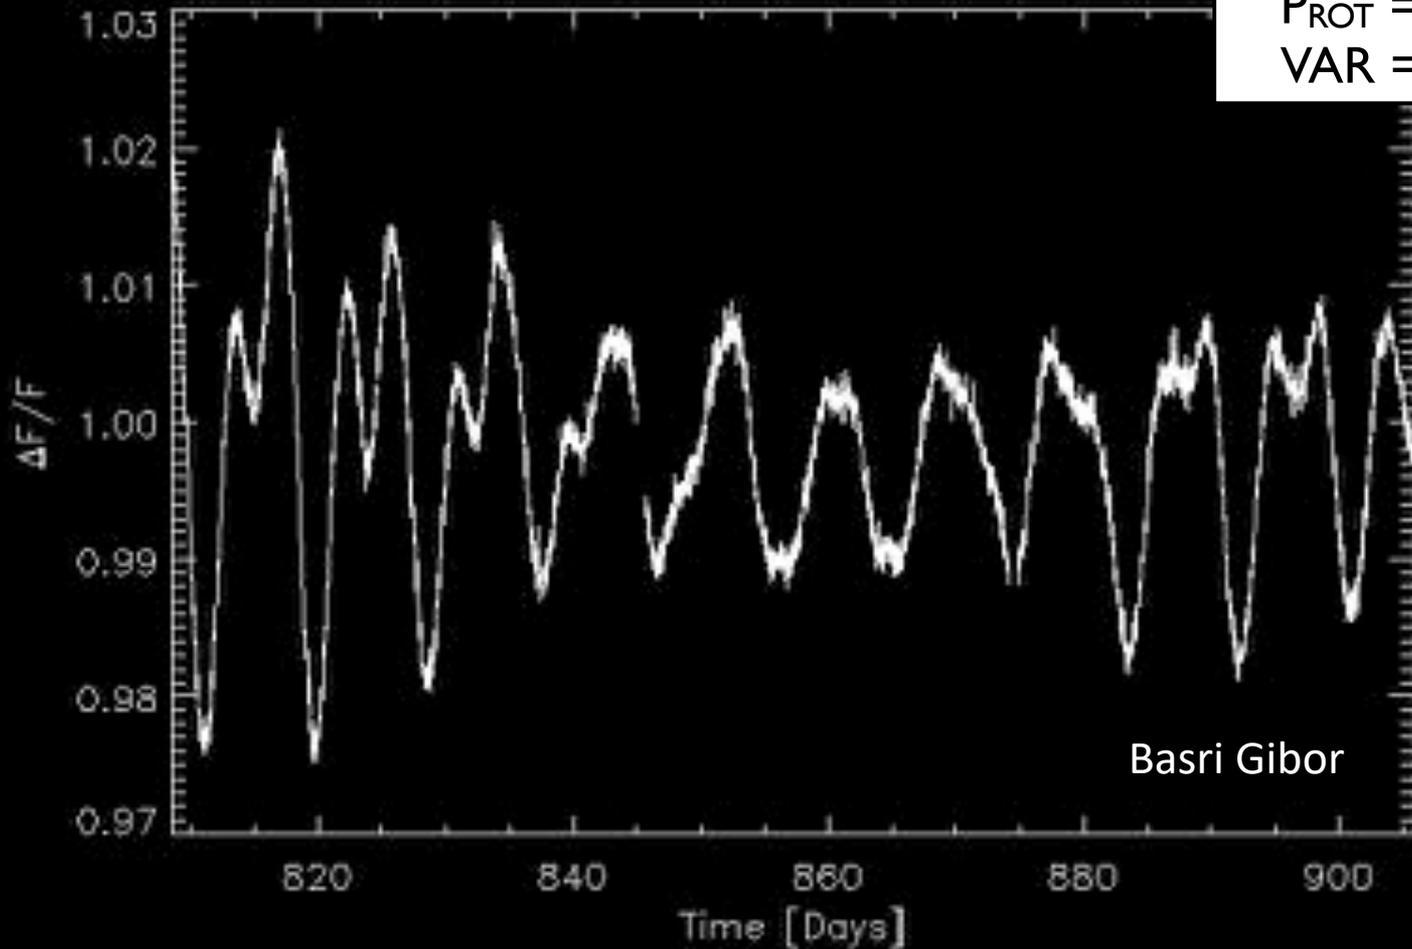

ROTATIONAL VARIABILITY AT A RANGE OF PERIODS

$T_{\text{EFF}} = 5360 \text{ K}$
 $P_{\text{ROT}} = 3.22 \text{ D}$
 $\text{VAR} = 2.5\%$

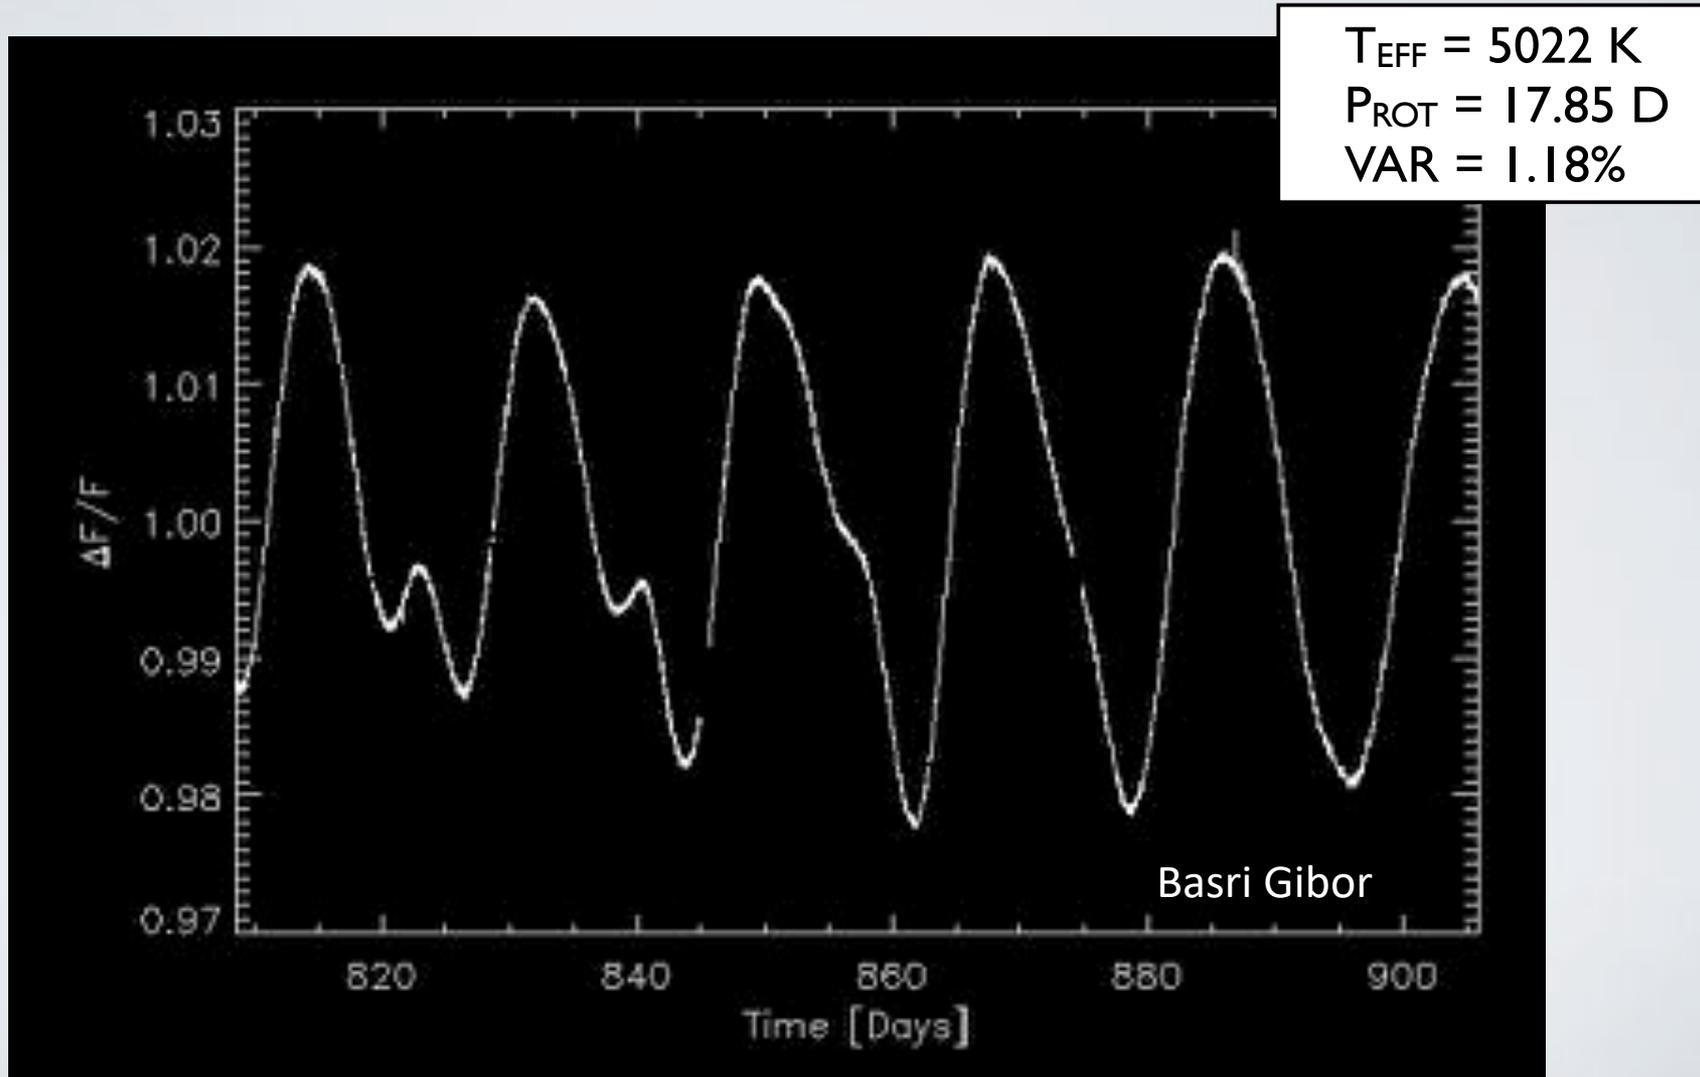

ROTATIONAL VARIABILITY AT A RANGE OF PERIODS

$T_{\text{EFF}} = 4288 \text{ K}$
 $P_{\text{ROT}} = 8.96 \text{ D}$
 $\text{VAR} = 1.25\%$

Double-Dipping: A New Relation between Stellar Rotation and Starspot Activity

“Combination of spot coverage and lifetime” Gibor Basri, Hieu T. Nguyen (May 2018)

Stellar Rotation measurements

The rotation period can be determined via

1. Lomb-Scargle periodograms: 2. Autocorrelation functions

Lomb (1976), Scargle (1982) and Zechmeister & Kurster (2009).

Most activity-induced signals will show some quasi-periodicity with a recurrence timescale related to the stellar rotation period, P_{rot} and/or its harmonics.

Generalized LS

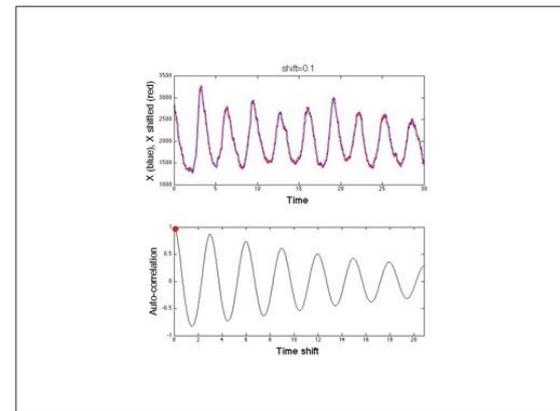

We can fit a sinusoid to our dataset:

$$m_i = A \cos(\omega t_i) + B \sin(\omega t_i) + C,$$

Edelson & Krolik, 1988.

Star's activity identity card:

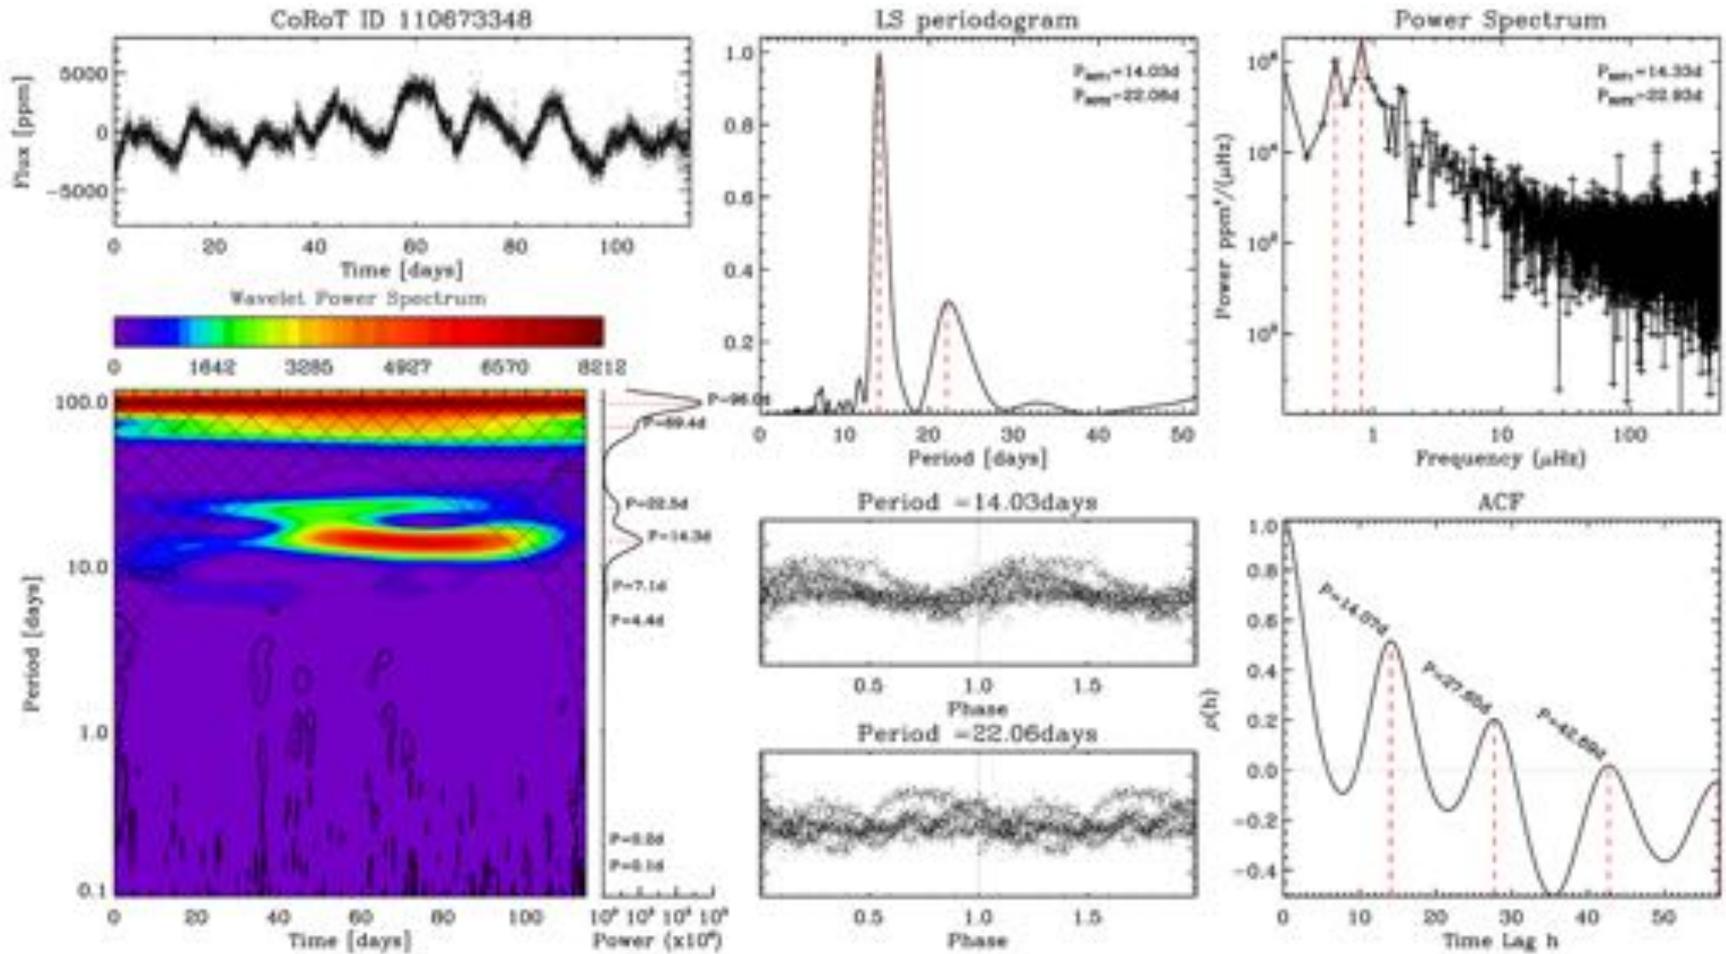

$$K_{ij} = \frac{(y_i - \bar{y})(y_j - \bar{y})}{(\sigma_i \sigma_j)^{1/2}}$$

KEPLER Targets

Stellar rotation periods

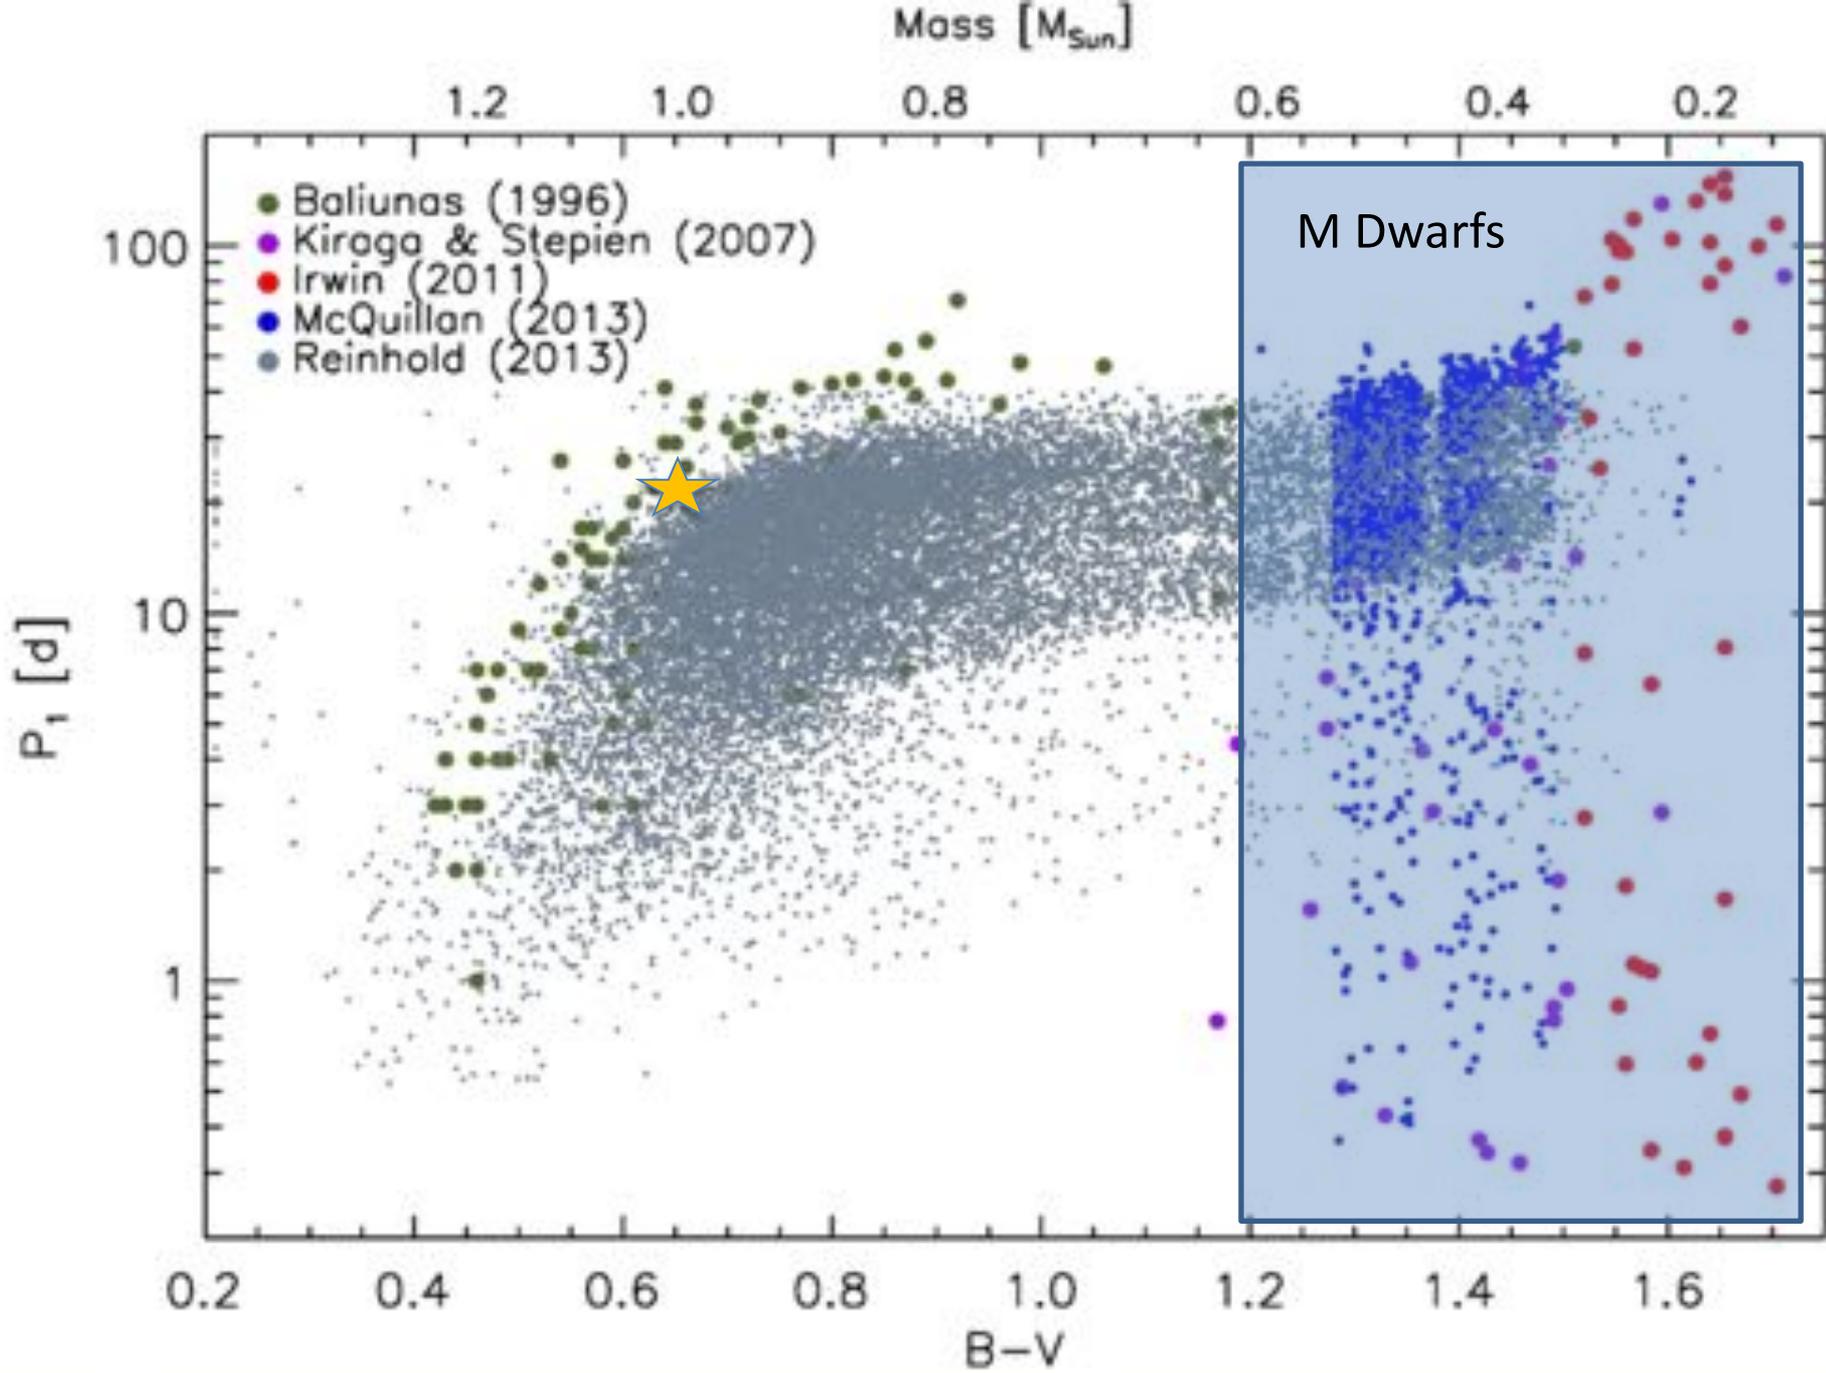

- Good agreement overall for short period (active stars)
- Few cases, especially at long periods, the period identified via Lomb-Scargle is twice as long as that of the autocorrelation
- Use stellar rotation period obtained when both agrees (not perfect).
- The majority of the old stars in our sample show very little photometric variations. 0.01 parts per thousand
- Difficult to measure the rotation period for old stars

ABSTRACT

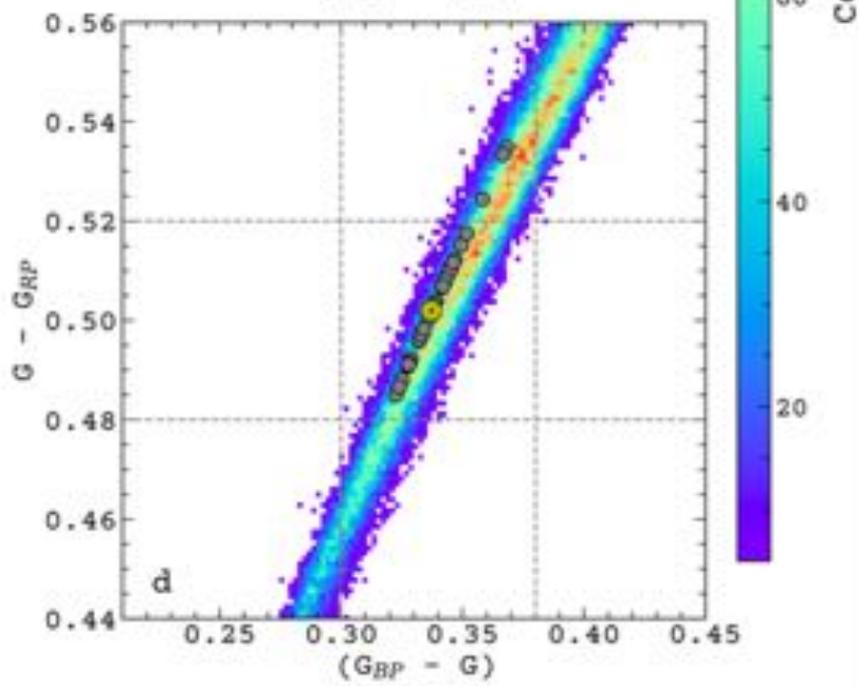

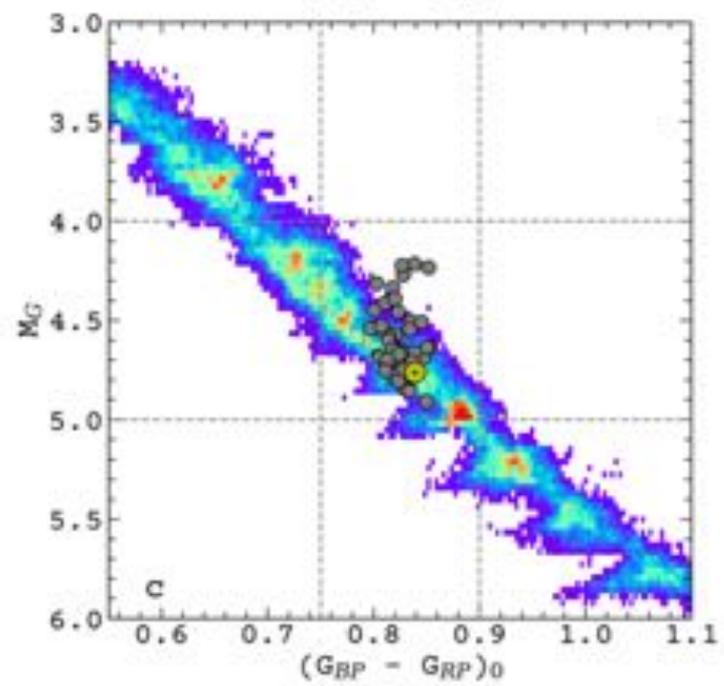

A major issue to interpret the rotation period distribution for main sequence stars by using Kepler mission data has been the lack of precise evolutionary status for those objects. We present here evolutionary status based on Gaia Data Release 2 parallaxes and photometry for 2,573 stars. Our results show that the rotation periods of these stars are similar to those of the Sun. Those values from Kepler mission data are not the root cause of the observed rotation period distribution. This is due to the selection criteria used in the Kepler mission. This is the first time that the rotation periods of these stars are compared with the Sun. This is the first time that the rotation periods of these stars are compared with the Sun. This is the first time that the rotation periods of these stars are compared with the Sun.

“A major issue to interpret the rotation period and activity behavior for main sequence stars by using Kepler mission data has been the lack of precise evolutionary status for those objects and the understand of selections criteria.”

Conclusions

- We need a selection criteria for benchmark stars.

Ex: rotation – activity – Age

Pre-Main-Sequence (PMS)

Main-sequence stars (MS)

Subgiants (SgB) > 35 days

Giants (?)

- Rotation Periods from 0.5 to 150 days;
- Covering a range of parameters
- KEPLER photometry activity proxy?
- Distinguishing main sequence / subgiants

Reliable stellar rotational periods for a large sample of old stars (as old as the Sun).

it is possible?

Conclusion

- Benchmark stars according the scientific purposes and datasets possibilities
- Pick up some “golden” stars to be follow-up intensively
- Better understand physical processes on those targets (facula, spots dynamics)
- Optimize It is mandatory , as a well a connection between other PLATO Work packages
- Benchmark stars from Clusters [like NGC 6811 (1 Gyr) and M67 (4 Gyr): homogeneous population]:
Gaia perspectives
